#### **Front-End Development**

#2 Learn Once, Write Anywhere

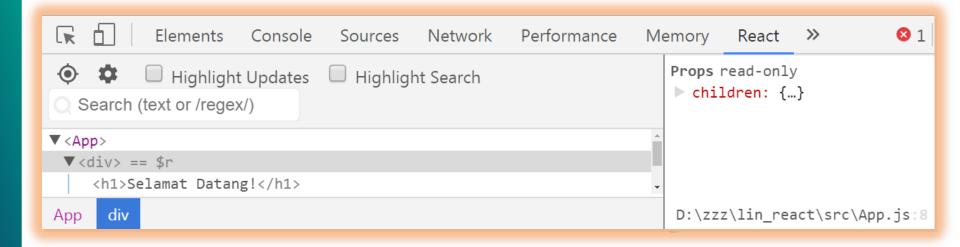

#### **React Dev Tools**

Add React Dev Tools on Chrome from: https://chrome.google.com/webstore/

# **State & Props**

- There are 2 types of data that control a component: *State & Props*.
- Props are set by the parent and they're fixed throughout the lifetime of a component. For data that is going to change, we have to use State.

# **State**

- In general, we should initialize state in the constructor, and then call setState when we want to change it.
- State is mutable, and defines at any given time, the current state of the React component that is being rendered.

# src/App.js

```
import React, { Component } from 'react';
class App extends Component {
   render() {
      return (
          <h1>Selamat datang!</h1>
                             (i) localhost:3000
                       |Selamat datang!
export default App;
```

### State #1

```
import React, { Component } from 'react';
class App extends Component {
   constructor(){
      super();
      this.state = {nama:'Andi'};
   render() {
      return (
         <h1>Halo {this.state.nama}</h1>
                              (i) localhost:3000
                       Halo Andi
export default App;
```

### State #2

```
import React, { Component } from 'react';
class App extends Component {
   constructor(){
     super();
    this.state = {nama:'Andi', usia:21};
render() {
   return (
      <div>
         <h1>Halo {this.state.nama}</h1>
         <h1>Usia {this.state.usia} th</h1>
      </div>
                            Halo Andi
                            Usia 21 th
export default App;
```

src/App.js

## **Updating State**

```
import React, { Component } from 'react';
class App extends Component {
   constructor(){
      super();
      this.state = {nama:'Andi'};
   render() {
      setTimeout(() => {
         this.setState({nama: 'Budi'});
      }, 3000)
      return (
          <h1>Halo {this.state.nama}</h1>
                        ← → C (i) localhost:30
                                         ← → C ① localhost:30
export default App;
                       Halo Andi
                                        lHalo Budi
```

# **Props**

- Most components can be customized with different parameters when they are created. These creation parameters are called *Props (Properties)*.
- It lets you make a component that is used in many different places in your app, with slightly different properties in each places.
- For short, props are static properties on a React component that are immutable (cannot be changed).

```
import React, { Component } from 'react';
import Footer from './component/Footer';
class App extends Component {
  render() {
    var teks = "Hak cipta dilindungi";
    return (
      <div>
        <h1>Selamat datang!</h1>
       <Footer konten={teks} />
      </div>
export default App;
```

```
import React, { Component } from 'react';
class Footer extends Component {
  render() {
    return (
      <div>
        <h4>{this.props.konten}</h4>
      </div>
export default Footer;
```

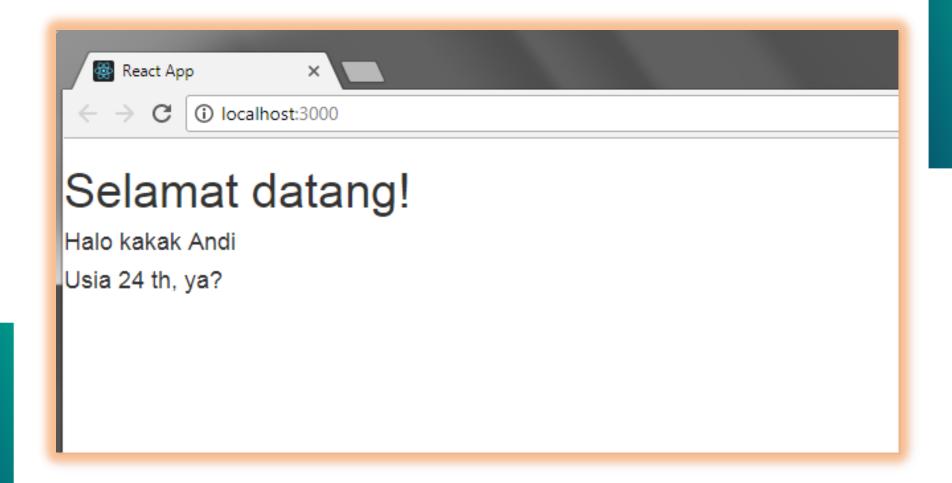

```
import React, { Component } from 'react';
import Footer from './component/Footer';
class App extends Component {
  render() {
    var andi = {nama:"Andi",usia:24};
    return (
      <div>
        <h1>Selamat datang!</h1>
        <Footer id={andi.nama} umur={andi.usia}/>
      </div>
export default App;
```

```
import React, { Component } from 'react';
class Footer extends Component {
  render() {
    return (
      <div>
        <h4>Halo kakak {this.props.id}</h4>
        <h4>Usia {this.props.umur} th, ya?</h4>
      </div>
export default Footer;
```

#### **State** → **Props**

```
import React, { Component } from 'react';
import Footer from './component/Footer';
class App extends Component {
  constructor(){
    super();
    this.state = {nama:'Andi'};
  render() {
    return (
      <div>
       <Footer id={this.state.nama} />
      </div>
export default App;
```

#### **State** → **Props**

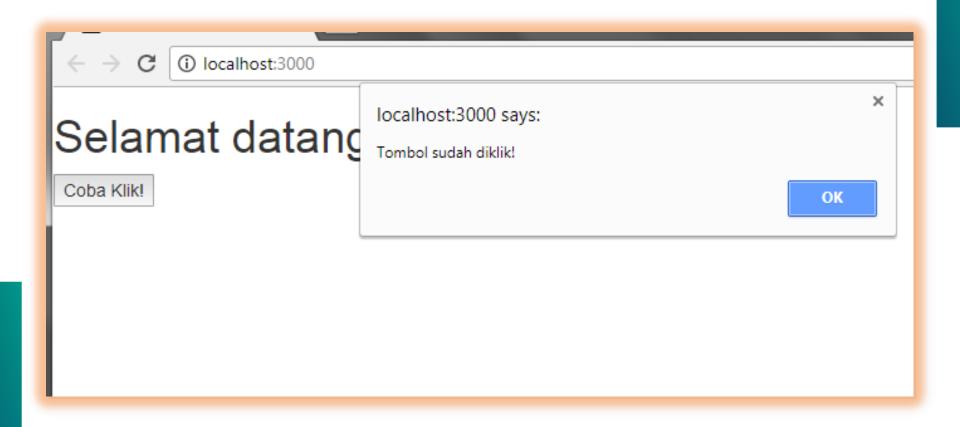

```
import React, { Component } from 'react';
class Footer extends Component {
  render() {
    return (
      <div>
        <h1>Halo {this.props.id}</h1>
      </div>
export default Footer;
```

# Handling Events

### **Click Event**

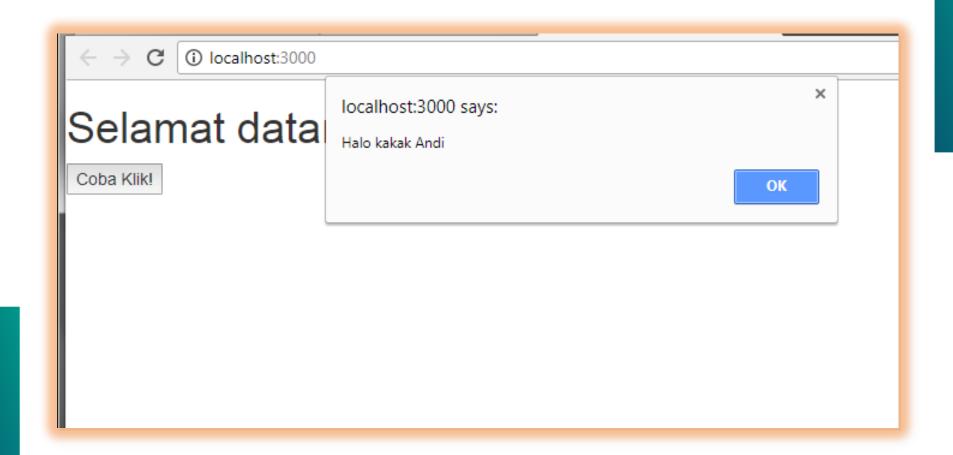

#### Click Event

```
import React, { Component } from 'react';
class App extends Component {
  klik(){
    alert('Tombol sudah diklik!');
  render() {
    return (
      <div>
        <h1>Selamat datang!</h1>
        <button onClick={this.klik}>
          Coba Klik!
        </button>
      </div>
export default App;
```

#### Click Event with param

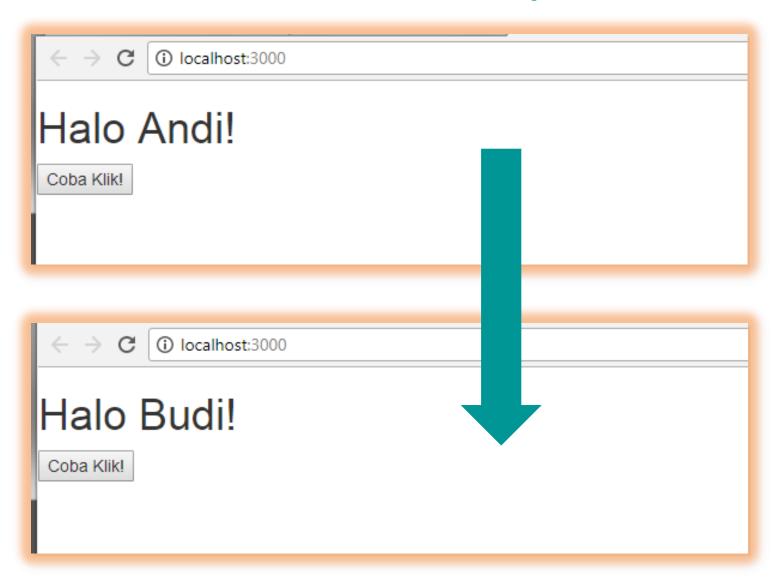

#### Click Event with param

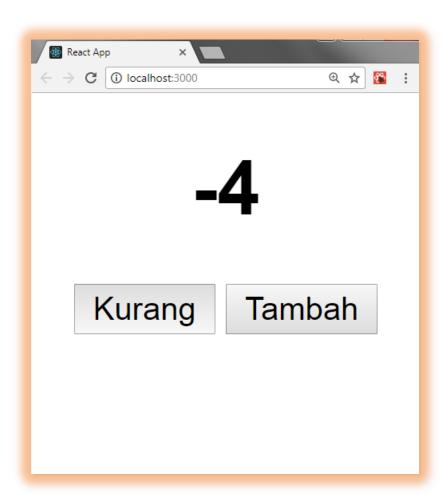

```
import React, { Component } from 'react';
class App extends Component {
  klik(siapa){
    alert('Halo kakak '+siapa);
 render() {
    return (
      <div>
        <h1>Selamat datang!</h1>
        <button onClick={()=>{this.klik('Andi');}}>
          Coba Klik!
        </button>
      </div>
export default App;
```

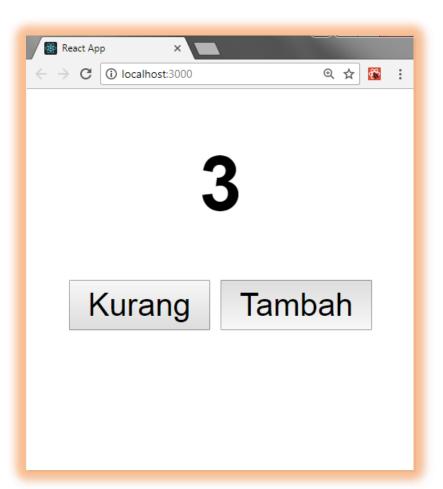

# Click Event update State #1

```
import React, { Component } from 'react';
class App extends Component {
  constructor(){
                                          src/App.js
    super();
    this.state = {user: 'Andi'};
                                      Click Event
  klik(siapa){
    this.setState({user:siapa});
                                    update State #1
  render() {
    return (
      <div>
        <h1>Halo {this.state.user}!</h1>
        <button onClick={()=>{this.klik('Budi');}}>
         Coba Klik!
        </button>
      </div>
export default App;
```

# Click Event update State #2

#### src/App.js

#### Click Event update State #2 Part 1

```
import React, { Component } from 'react';
class App extends Component {
  state = { count: 0 }
  tambah = () => {
    this.setState({
      count: this.state.count + 1
   });
  kurang = () => {
    this.setState({
      count: this.state.count - 1
   });
```

#### src/App.js

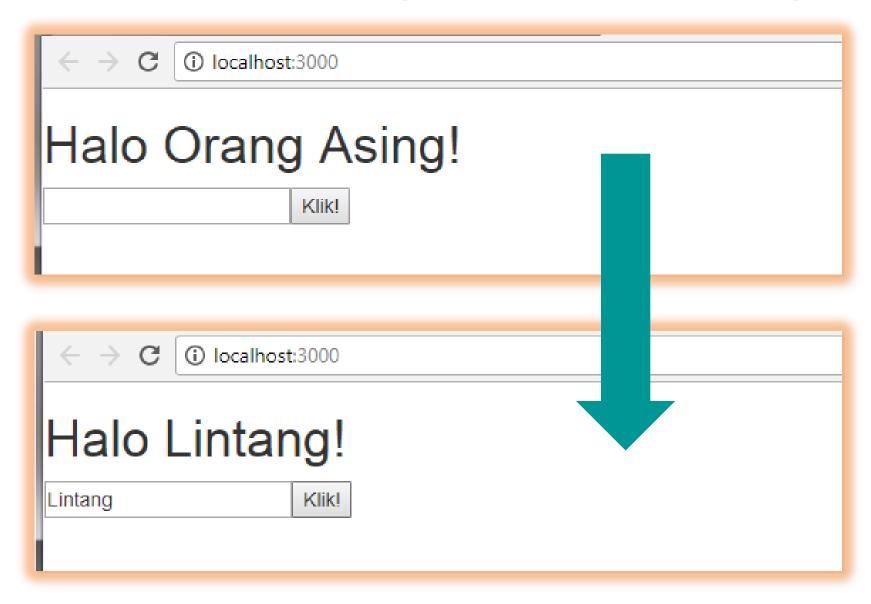

#### Click Event update State #2 Part 2

```
render(){
 return (
    <div>
    <center>
    <h1>{this.state.count}</h1>
    <div>
    <button onClick = {this.kurang}>Kurang</button>
    <span> </span>
    <button onClick = {this.tambah}>Tambah</button>
    </div>
    </center>
    </div>
```

export default App;

# Click Event update State from user input

#### src/App.js

# Click Event

update State from user input

```
import React, { Component } from 'react';
class App extends Component {
  constructor(){
    super();
    this.state = {user:'Orang Asing'};
  klik(){
    this.setState({user: this.refs.nama.value});
  render() {
    return (
      <div>
        <h1>Halo {this.state.user}!</h1>
        <input ref="nama" type="text"/>
        <button onClick={()=>{this.klik();}}>Klik!</button>
      </div>
export default App;
```

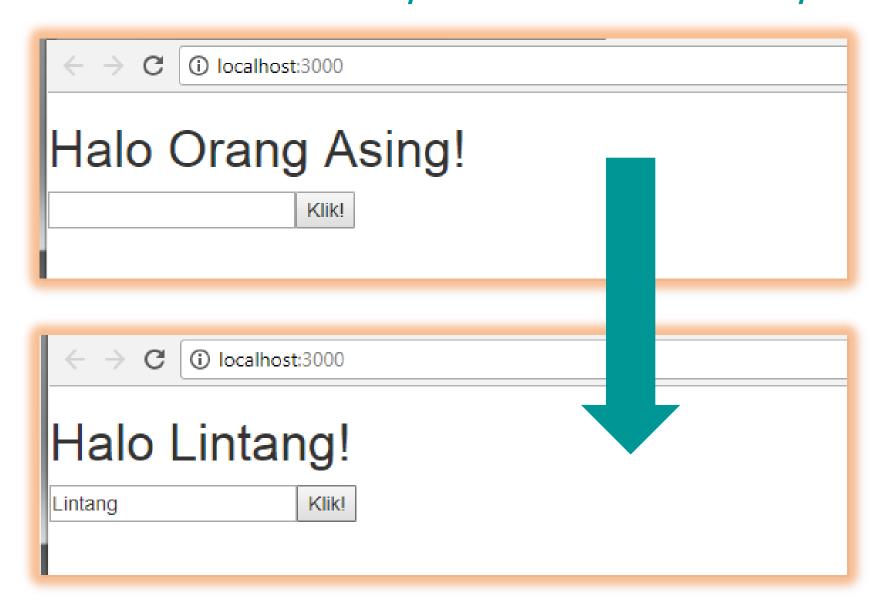

#### **Events**

- Keyboard Events onKeyDown onKeyPress onKeyUp
- Focus Events onFocus onBlur
- Form Events on Change on Input on Invalid on Submit
- Mouse Events

onClick onContextMenu onDoubleClick onDrag onDragEnd onDragEnter onDragExit onDragLeave onDragOver onDragStart onDrop onMouseDown onMouseEnter onMouseLeave onMouseMove onMouseOut onMouseOver onMouseUp

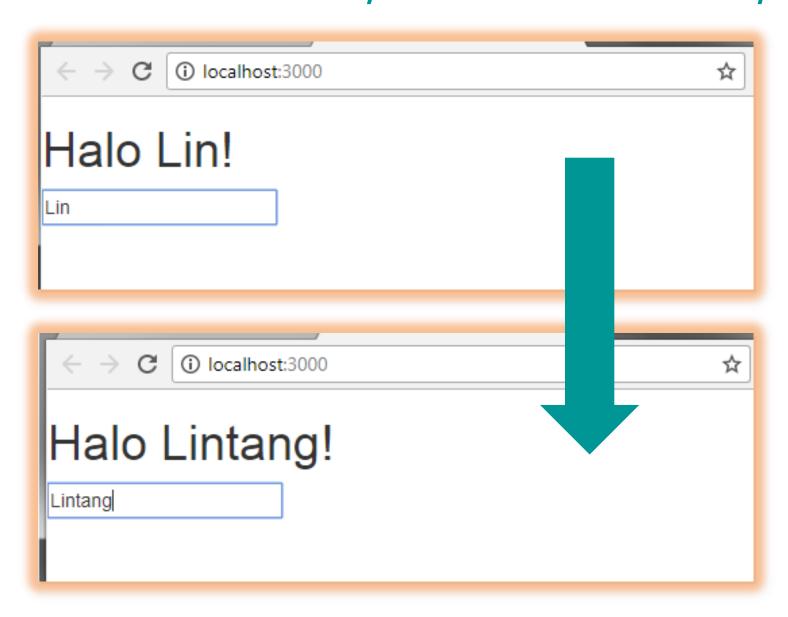

# Double Click Event update State from user input

```
src/App.js
import React, { Component } from 'react';
class App extends Component {
                                        Double Click
  constructor(){
    super();
                                            update State
   this.state = {user:'Orang Asing'};
                                          from user input
  klik(){
   this.setState({user: this.refs.nama.value});
  render() {
    return (
      <div>
        <h1>Halo {this.state.user}!</h1>
        <input ref="nama" type="text"/>
        <button onDoubleClick={()=>{this.klik();}}>
          KLik!
        </button>
      </div>
export default App;
```

# oninput Event update State from user input

#### src/App.js

#### onInput Event

update State from user input

```
import React, { Component } from 'react';
class App extends Component {
  constructor(){
    super();
    this.state = {user:'Orang Asing'};
  klik(){
    this.setState({user: this.refs.nama.value});
  render() {
    return (
      <div>
        <h1>Halo {this.state.user}!</h1>
        <input ref="nama" type="text"</pre>
         onInput={()=>{this.klik();}}/>
      </div>
export default App;
```

# Life-cycle Methods #1 Mounting

- componentWillMount(){}
- Invoked once on both client and server, immediately before the initial rendering occurs.
- componentDidMount(){}

Invoked once only on client, immediately after the initial rendering occurs.

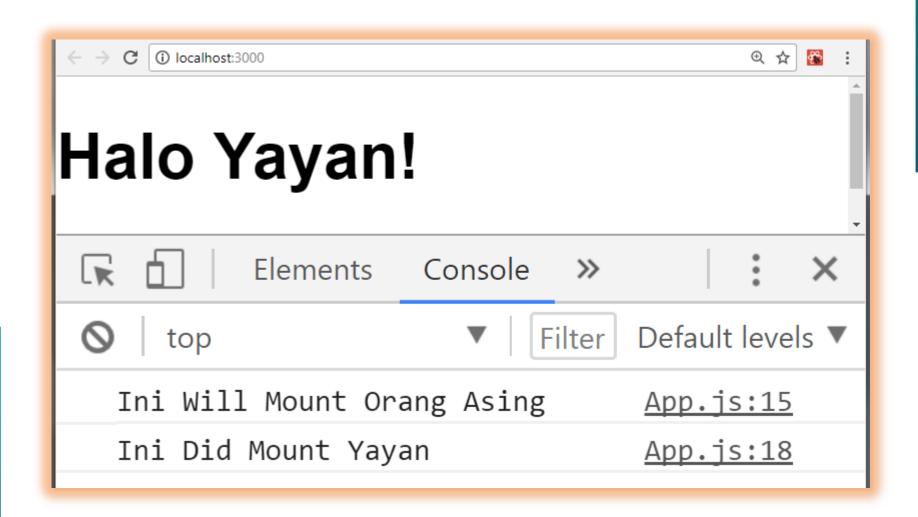

#### **Life-cycle Methods**

Mounting

```
import React, { Component } from 'react';
                                              src/App.js
class App extends Component {
  constructor(){
    super();
    this.state = {user:'Orang Asing'};
  }
  componentWillMount(){
    this.setState({user:'Yayan'});
    console.log('Ini Will Mount '+this.state.user);
  componentDidMount(){
    console.log('Ini Did Mount '+this.state.user);
  render() {
    return (
      <div><h1>Halo {this.state.user}!</h1></div>
export default App;
```

src/App.js

## Life-cycle Methods Mounting

# Life-cycle Methods #2 Updating

#### componentWillUpdate()

Invoked immediately before rendering when new props or state are being received. This isn't called for the initial render.

#### componentDidUpdate()

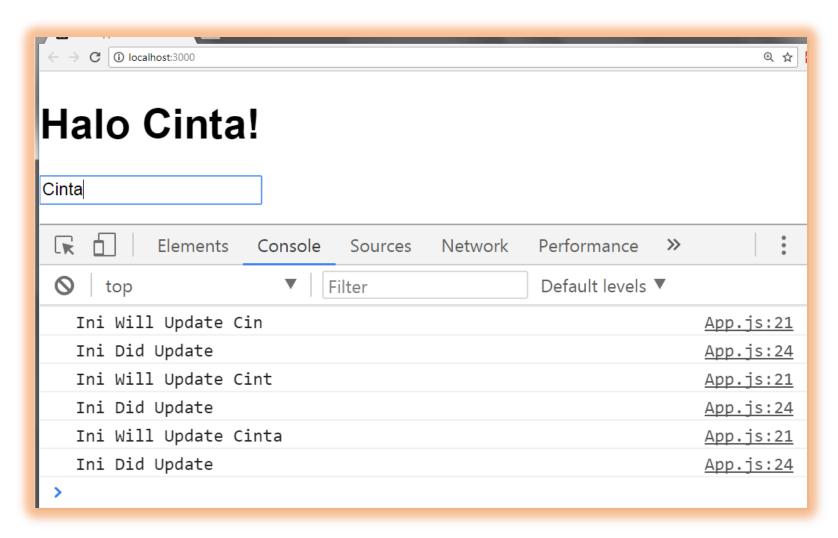

Invoked immediately after the component's updates are flushed to the DOM. This isn't called for the initial render.

```
Life-cycle
import React, { Component } from 'react';
                                                  Updating
class App extends Component {
  constructor(){
                                              src/App.js
    super();
    this.state = {user:'Orang Asing'};
  klik(){
    this.setState({user: this.refs.nama.value});
  componentWillUpdate(x, y){
    console.log('Ini Will Update '+y.user);
  componentDidUpdate(){
    console.log('Ini Did Update ');
  render() {
    return (
 <div><h1>Halo {this.state.user}!</h1>
 <input ref="nama" type="text" onInput={()=>{this.klik();}}/>
 </div>
  );}}
export default App;
```

src/App.js

## Life-cycle Methods Updating

### Router

- A router allows an application to navigate between different components, changing the browser URL, modifying the browser history, and keeping the UI state in sync.
- React focuses only on building user interfaces, so it doesn't have a built-in solution for routing.
- We can use React Router DOM, which allows us to define routes on our web app. First, install this package on our React project directory:

\$ npm install react-router-dom --save

### Routing

- Beranda
- Header
- Article
- Footer

Ini Header

- Beranda
- Header
- Article
- Footer

Ini Article

(i) localhost:3000/footer

#### Coba Routing

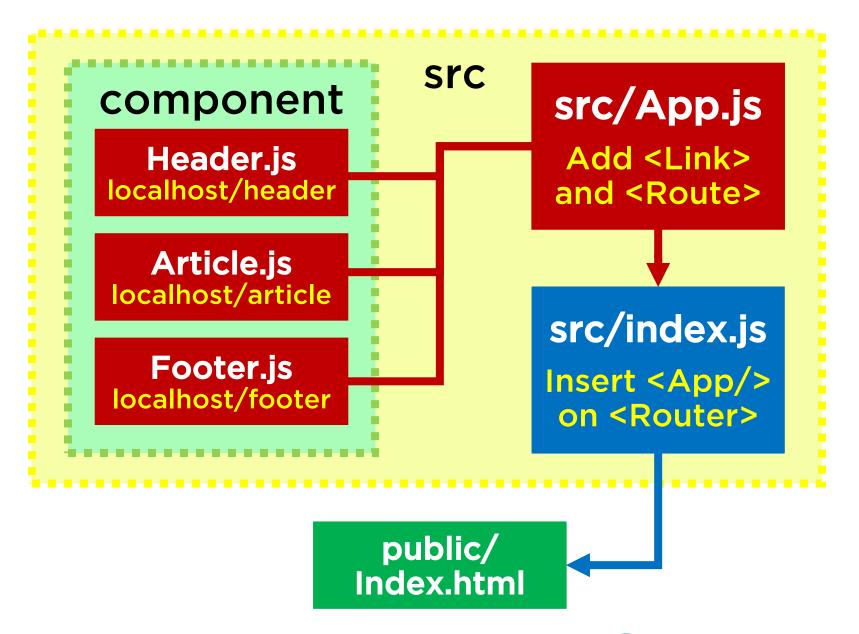

- Beranda
- Header
- Article
- Footer

Ini Footer

Header.js localhost/header Article.js
localhost/article

Footer.js
localhost/footer

# src/component/Header.js #1 component

```
import React, { Component } from 'react';
class Header extends Component {
   render() {
      return (
         <h1>Ini Header!</h1>
export default Header;
```

### src/component/Article.js #2 component

```
import React, { Component } from 'react';
class Article extends Component {
   render() {
      return (
         <h1>Ini Article!</h1>
export default Article;
```

### src/component/Footer.js #3 component

```
import React, { Component } from 'react';
class Footer extends Component {
   render() {
      return (
         <h1>Ini Footer!</h1>
export default Footer;
```

## src/index.js Insert Router!

```
import React from 'react';
import ReactDOM from 'react-dom';
import './index.css';
import App from './App';
import registerServiceWorker from
'./registerServiceWorker';
import { BrowserRouter } from 'react-router-dom';
ReactDOM.render(
  <BrowserRouter>
    <App />
  </BrowserRouter>,
document.getElementById('root'));
registerServiceWorker();
```

# src/App.js Part 1 Import

```
import React, { Component } from 'react';
import { Link, Route } from 'react-router-dom';
import Header from './component/Header';
import Footer from './component/Footer';
import Article from './component/Article';
```

## src/App.js Part 2 Insert Link

```
class App extends Component {
render() {
return (
<div>
<h1>Coba Routing</h1>
<l
<Link to="/">Beranda</Link>
<Link to="/header">Header</Link>
<Link to="/article">Article
<Link to="/footer">Footer
```

## src/App.js Part 3 Insert Route

```
<div>
       path="/" component={'Home'}/>
<Route
<Route path="/article" component={Article}/>
<Route path="/header" component={Header}/>
<Route path="/footer" component={Footer}/>
</div>
</div>
export default App;
```

### Routing

- Beranda
- Header
- Article
- Footer

Ini Header

- Beranda
- Header
- Article
- Footer

Ini Article

(i) localhost:3000/footer

#### Coba Routing

- Beranda
- Header
- Article
- Footer

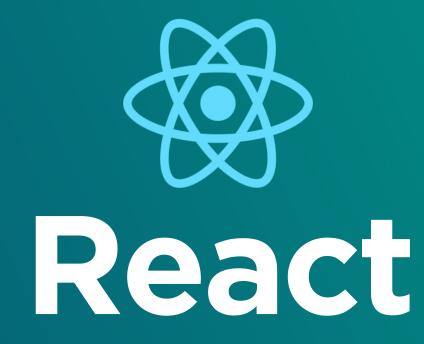

Ini Footer

Header.js localhost/header Article.js
localhost/article

Footer.js
localhost/footer
